# Many-Electron Integrals over Gaussian Basis Functions. I. Recurrence Relations for Three-Electron Integrals 

Giuseppe M. J. Barca, Pierre-François Loos,* and Peter M. W. Gill*<br>Research School of Chemistry, Australian National University, Australian Capital Territory 2601, Australia

#### Abstract

Explicitly correlated F12 methods are becoming the first choice for high-accuracy molecular orbital calculations and can often achieve chemical accuracy with relatively small Gaussian basis sets. In most calculations, the many three- and four-electron integrals that formally appear in the theory are avoided through judicious use of resolutions of the identity (RI). However, for the intrinsic accuracy of the F12 wave function to not be jeopardized, the associated RI auxiliary basis set must be large. Here, inspired by the Head-Gordon-Pople and PRISM algorithms for two-electron integrals, we present an algorithm to directly compute threeelectron integrals over Gaussian basis functions and a very general class of three-electron operators without invoking RI approximations. A general methodology to derive vertical, transfer, and horizontal recurrence relations is also presented.

## 1. INTRODUCTION

Many years ago, Kutzelnigg ${ }^{1}$ showed that introducing the interelectronic distance $r_{12}=\left|\mathbf{r}_{1}-\mathbf{r}_{2}\right|$ into a simple wave function $\Psi_{0}$ for the helium atom yields

$$
\begin{equation*}
\Psi=\left(1+\frac{r_{12}}{2}\right) \Psi_{0}+\chi\left(\mathbf{r}_{1}, \mathbf{r}_{2}\right) \tag{1}
\end{equation*}
$$

where $\chi\left(\mathbf{r}_{1}, \mathbf{r}_{2}\right)$ is expanded in a determinantal basis, and dramatically improves the convergence of second-order perturbation theory, ${ }^{2}$ coupled cluster, ${ }^{3}$ and other variational calculations. ${ }^{4}$ This approach, which gave birth to the so-called "R12 methods" $2,5,6$ is a natural extension of pioneering work by Hylleraas in the 1920s. ${ }^{7,8}$

Kutzelnigg's idea was later generalized to more accurate correlation factors $f_{12} \equiv f\left(r_{12}\right) .{ }^{9-14}$ Nowadays, a popular choice for $f_{12}$ is a Slater-type geminal ${ }^{15}$ (STG)

$$
\begin{equation*}
f_{12}^{S T G}=\exp \left(-\lambda r_{12}\right) \tag{2}
\end{equation*}
$$

which is sometimes expanded as a linear combination of Gaussian-type geminals ${ }^{9,10}$ (GTG)

$$
\begin{equation*}
f_{12}^{\mathrm{STG}} \approx \sum_{k=1}^{N_{\mathrm{G}}} c_{k} f_{12}^{\mathrm{GTG}}\left(\lambda_{k}\right)=\sum_{k=1}^{N_{\mathrm{G}}} c_{k} \exp \left(-\lambda_{k} r_{12}^{2}\right) \tag{3}
\end{equation*}
$$

for computational convenience. ${ }^{11,13,14}$
The resulting "F12 methods" achieve chemical accuracy for small organic molecules with relatively small Gaussian basis sets ${ }^{16-20}$ and are quickly becoming the first-choice nonstochastic method for high accuracy. ${ }^{19,20}$ They are now appearing within state-of-the-art composite procedures. ${ }^{21}$

However, whereas a conventional (nonexplicitly correlated) calculation using $N$ Gaussian one-electron basis functions leads to an energy expression with $O\left(N^{4}\right)$ relatively easy two-electron
integrals, ${ }^{22-32}$ the explicitly correlated wave function has an energy expression with $O\left(N^{6}\right)$ three-electron integrals and $O\left(N^{8}\right)$ four-electron integrals. These many-electron integrals are known in closed form in a few special cases; ${ }^{33}$ however, in general, they are computationally expensive, and the task of computing $O\left(N^{6}\right)$ or $O\left(N^{8}\right)$ of them appears overwhelming.

To render F12 methods computationally tractable and to avoid these three- and four-electron integrals without introducing unacceptable errors, Kutzelnigg and Klopper ${ }^{2}$ proposed to insert the resolution of the identity (RI)

$$
\begin{equation*}
\hat{I} \approx \sum_{\mu}^{N_{\mathrm{RI}}}\left|\chi_{\mu}\right\rangle\left\langle\chi_{\mu}\right| \tag{4}
\end{equation*}
$$

into the three- or four-electron operators. ${ }^{17,34}$ In this way, three- and four-electron integrals are expanded in terms of oneand two-electron integrals that can be found efficiently using conventional quantum chemistry software.

Of course, the approximation (eq 4) introduces chemically acceptable errors only if the auxiliary basis set $\left\{\chi_{\mu}\right\}$ is sufficiently large $\left(N_{\mathrm{RI}} \gg N\right)$. (For example, for the leflunomide molecule $\mathrm{C}_{12} \mathrm{H}_{9} \mathrm{~F}_{3} \mathrm{~N}_{2} \mathrm{O}_{2}$ studied recently by Bachorz et al., ${ }^{35}$ the primary aug-cc-pVTZ and auxiliary ${ }^{36,37}$ basis sets have 1081 and 2864 basis functions, respectively.) This realization has fueled much research, and there now exist very efficient RI formulations based on highly optimized auxiliary basis sets $(\mathrm{ABS})^{38}$ and complementary ABS (CABS). ${ }^{39}$ However, to achieve millihartree accuracy, such bases must be approximately complete up to $3 L_{\text {occ }}{ }^{17}$ where $L_{\text {occ }}$ is the highest angular momentum of basis functions in the orbital basis set associated with the occupied molecular orbitals. Even if this requirement

Received: February 4, 2016
Published: March 16, 2016
can be reduced to $2 L_{\text {occ }}$ by density fitting, ${ }^{40}$ it remains demanding in cases (e.g., for transition metals) where high angular momenta are needed in the orbital basis.

For two reasons, however, we believe that the RI tactic can be avoided. First, the number of significant (i.e., greater than a threshold) three- and four-electron integrals is significantly smaller than $O\left(N^{6}\right)$ and $O\left(N^{8}\right)$, respectively. Second, the task of computing many-electron integrals over Gaussian basis functions is less formidable than many believe. For example, for three-electron integrals, a reduction of the computational effort from $O\left(N^{6}\right)$ to $O\left(N^{4}\right)$ is already achievable by exploiting robust density fitting techniques. ${ }^{41}$

Although there are $O\left(N^{4}\right)$ two-electron integrals, it is wellknown to quantum chemistry programmers that the number of significant two-electron integrals in a large system is only $O\left(N^{2}\right)$ if the two-electron operator is long-range ${ }^{42-44}$ and $O(N)$ if it is short-range. ${ }^{45,46}$ Similar considerations apply to many-electron integrals, and one can show that the number of significant three- and four-electron integrals is only $O\left(N^{3}\right)$ and $O\left(N^{4}\right)$, respectively, even for long-range operators. (For shortrange operators, there are even fewer.) Thus, if we can find good algorithms for identifying and computing the tiny fraction of many-electron integrals that are significant, large-scale calculations using F12 methods will become feasible without the need for the RI approximation.

The present manuscript is the first of a series on manyelectron integrals. Here, we present an algorithm to compute integrals over three-electron operators using recurrence relations (RRs). The second paper ${ }^{47}$ in the series will discuss the construction of upper bounds and effective screening strategies, and the third ${ }^{48}$ will describe optimized numerical methods for the efficient generation of [ssslsss] integrals. Our recursive approach applies to a general class of multiplicative three-electron operators and thus generalizes existing schemes that pertain only to GTGs. ${ }^{10,49-54}$

Section 2 contains basic definitions, classifications of threeelectron operators, and permutational symmetry considerations. In section 3, we propose a recursive algorithm for the computation of three-electron integrals. Details of a general scheme for deriving three-electron integral RRs are presented in the Appendix. Atomic units are used throughout.

## 2. THREE-ELECTRON INTEGRALS

A primitive Gaussian-type orbital (PGTO)

$$
\begin{equation*}
\varphi_{\mathbf{a}}^{\mathbf{A}}(\mathbf{r})=\left(x-A_{x}\right)^{a_{x}}\left(y-A_{y}\right)^{a_{y}}\left(z-A_{z}\right)^{a_{z}} e^{-\alpha|\mathbf{r}-\mathbf{A}|^{2}} \tag{5}
\end{equation*}
$$

is defined by its exponent $\alpha$, its center $\mathbf{A}=\left(A_{x}, A_{y}, A_{z}\right)$, its angular momentum vector $\mathbf{a}=\left(a_{x}, a_{y}, a_{z}\right)$, and its total angular momentum $a=a_{x}+a_{y}+a_{z}$.

A contracted Gaussian-type orbital (CGTO) $\psi_{a}^{A}(\mathbf{r})$ is a linear combination of $K_{A}$ PGTOs. We are interested in the threeelectron operator

$$
\begin{equation*}
f_{12} g_{13} h_{23} \equiv f\left(r_{12}\right) g\left(r_{13}\right) h\left(r_{23}\right) \tag{6}
\end{equation*}
$$

and we write the integral of six CGTOs over this as

$$
\begin{align*}
\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle \equiv & \left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right| f_{12} g_{13} h_{23}\left|\mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle \\
= & \iiint \psi_{\mathbf{a}_{1}}^{\mathbf{A}_{1}}\left(\mathbf{r}_{1}\right) \psi_{\mathbf{a}_{2}}^{\mathbf{A}_{2}}\left(\mathbf{r}_{2}\right) \psi_{\mathbf{a}_{3}}^{\mathbf{A}_{3}}\left(\mathbf{r}_{3}\right) \\
& f_{12} g_{13} h_{23} \psi_{\mathbf{b}_{1}}^{\mathbf{B}_{1}}\left(\mathbf{r}_{1}\right) \psi_{\mathbf{b}_{2}}^{\mathbf{B}_{2}}\left(\mathbf{r}_{2}\right) \psi_{\mathbf{b}_{3}}^{\mathbf{B}_{3}}\left(\mathbf{r}_{3}\right) \mathrm{d} \mathbf{r}_{1} \mathrm{~d} \mathbf{r}_{2} \mathrm{~d} \mathbf{r}_{3} \tag{7}
\end{align*}
$$

We will use square brackets if the integral is over PGTOs

$$
\begin{align*}
{\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right] \equiv } & {\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\left|f_{12} g_{13} h_{23}\right| \mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right] } \\
= & \iiint \varphi_{\mathbf{a}_{1}}^{\mathbf{A}_{1}}\left(\mathbf{r}_{1}\right) \varphi_{\mathbf{a}_{2}}^{\mathbf{A}_{2}}\left(\mathbf{r}_{2}\right) \varphi_{\mathbf{a}_{3}}^{\mathbf{A}_{3}}\left(\mathbf{r}_{3}\right) \\
& f_{12} g_{13} h_{23} \varphi_{\mathbf{b}_{1}}^{\mathbf{B}_{1}}\left(\mathbf{r}_{1}\right) \varphi_{\mathbf{b}_{2}}^{\mathbf{B}_{2}}\left(\mathbf{r}_{2}\right) \varphi_{\mathbf{b}_{3}}^{\mathbf{B}_{3}}\left(\mathbf{r}_{3}\right) \mathrm{d} \mathbf{r}_{1} \mathrm{~d} \mathbf{r}_{2} \mathrm{~d} \mathbf{r}_{3} \tag{8}
\end{align*}
$$

and the fundamental integral (i.e., one in which all six PGTOs are $s$-type) is therefore

$$
\begin{equation*}
[\mathbf{0 0 0 | 0 0 0}]=S_{1} S_{2} S_{3} \iiint \varphi_{\mathbf{0}}^{\mathbf{Z}_{1}}\left(\mathbf{r}_{1}\right) \varphi_{\mathbf{0}}^{\mathbf{Z}_{2}}\left(\mathbf{r}_{2}\right) \varphi_{\mathbf{0}}^{\mathbf{Z}_{3}}\left(\mathbf{r}_{3}\right) f_{12} g_{13} h_{23} \mathrm{~d} \mathbf{r}_{1} \mathrm{~d} \mathbf{r}_{2} \mathrm{~d} \mathbf{r}_{3} \tag{9}
\end{equation*}
$$

where the exponents $\zeta_{i}$, centers $\mathbf{Z}_{i}$, and prefactors $S_{i}$ of the Gaussian product rule for the three electrons are

$$
\begin{align*}
& \zeta_{i}=\alpha_{i}+\beta_{i}  \tag{10}\\
& \mathbf{Z}_{i}=\frac{\alpha_{i} \mathbf{A}_{i}+\beta_{i} \mathbf{B}_{i}}{\alpha_{i}+\beta_{i}}  \tag{11}\\
& S_{i}=\exp \left[-\frac{\alpha_{i} \beta_{i}}{\alpha_{i}+\beta_{i}}\left|\mathbf{A}_{i}-\mathbf{B}_{i}\right|^{2}\right] \tag{12}
\end{align*}
$$

For conciseness, we will adopt a notation in which missing indices represent s-type Gaussians. For example, $\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]$ is shorthand for $\left[\mathbf{0 a}_{2} \mathbf{a}_{3} \mid \mathbf{0 0 0}\right]$. We will also use non-bold indices, e.g., $\left\langle a_{1} a_{2} a_{3} \mid b_{1} b_{2} b_{3}\right\rangle$ to indicate a complete class of integrals from a shell-sextet.
2.1. Three-Electron Operators. We are particularly interested in two types of three-electron operators: "chain" operators of the form $f_{12} g_{13}$ and "cyclic" operators of the form $f_{12} g_{13} h_{23}$. In both types, the most interesting cases arise when ${ }^{2,16-18}$

$$
f_{12}, g_{12}, h_{12}= \begin{cases}r_{12}^{-1}, & \text { Coulomb operator } \\ r_{12}, & \text { anti-Coulomb operator } \\ \exp \left(-\lambda r_{12}\right), & \text { Slater-type geminal } \\ \exp \left(-\lambda r_{12}^{2}\right), & \text { Gaussian-type geminal }\end{cases}
$$

and various combinations of these produce three-electron integrals of practical importance. We note that, by virtue of the identity $r_{12} \equiv r_{12}^{-1}\left(r_{1}^{2}+r_{2}^{2}-2 \mathbf{r}_{1} \cdot \mathbf{r}_{2}\right)$, integrals involving the antiCoulomb operator can be reduced to linear combinations of integrals over the Coulomb operator.
2.2. Permutational Symmetry. For real basis functions, it is known ${ }^{55}$ that two-electron integrals have 8 -fold permutational symmetry, meaning that the integrals

$$
\begin{array}{llll}
\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mid \mathbf{b}_{1} \mathbf{b}_{2}\right\rangle & \left\langle\mathbf{b}_{1} \mathbf{a}_{2} \mid \mathbf{a}_{1} \mathbf{b}_{2}\right\rangle & \left\langle\mathbf{b}_{1} \mathbf{b}_{2} \mid \mathbf{a}_{1} \mathbf{a}_{2}\right\rangle & \left\langle\mathbf{a}_{1} \mathbf{b}_{2} \mid \mathbf{b}_{1} \mathbf{a}_{2}\right\rangle \\
\left\langle\mathbf{a}_{2} \mathbf{a}_{1} \mid \mathbf{b}_{2} \mathbf{b}_{1}\right\rangle & \left\langle\mathbf{b}_{2} \mathbf{a}_{1} \mid \mathbf{a}_{2} \mathbf{b}_{1}\right\rangle & \left\langle\mathbf{b}_{2} \mathbf{b}_{1} \mid \mathbf{a}_{2} \mathbf{a}_{1}\right\rangle & \left\langle\mathbf{a}_{2} \mathbf{b}_{1} \mid \mathbf{b}_{2} \mathbf{a}_{1}\right\rangle
\end{array}
$$

are all equal. Three-electron integrals also exhibit permutational symmetry, and for computational efficiency, it is important that this be fully exploited. The degeneracy depends on the nature of the three-electron operator, and the five possible cases are listed in Table 1.

## 3. ALGORITHM

In this section, we present a recursive algorithm for generating a class of three-electron integrals of arbitrary angular momentum from an initial set of fundamental integrals. The algorithm

Table 1. Permutational Degeneracy for Various Operators

| type | operator | degeneracy |
| :---: | :--- | :---: |
| two-electron | $f_{12}$ | 8 |
| three-electron chain | $f_{12} g_{13}$ | 8 |
|  | $f_{12} f_{13}$ | 16 |
| three-electron cyclic | $f_{12} g_{13} h_{23}$ | 8 |
|  | $f_{12} f_{13} h_{23}$ | 16 |
|  | $f_{12} f_{13} f_{23}$ | 48 |

applies to any three-electron operator of the form $f_{12} g_{13} h_{23}$ and generalizes the HGP-PRISM algorithm following a OTTTCCCTTT pathway. ${ }^{28,31}$ The algorithm is shown schematically in Figure 1.

Figure 1. PRISM representation ${ }^{31}$ of a scheme for computing a threeelectron integral class. In this work, we consider the (orange) OTTTCCCTTT path.

After selecting a significant shell-sextet, we create a set of generalized fundamental integrals $[0]^{\mathrm{m}}$ (step O ). Next, we build angular momentum on center $\mathbf{A}_{3}$ (step $\mathrm{T}_{1}$ ) and on center $\mathbf{A}_{2}$ (step $\mathrm{T}_{2}$ ) using vertical RRs (VRRs). This choice is motivated by the fact that, for chain operators, the VRR for building momentum on $\mathbf{A}_{1}$ is more expensive than that for building on $\mathbf{A}_{2}$ and $\mathbf{A}_{3}$ (see Appendix). Then, using transfer RRs (TRRs), we transfer momentum onto $\mathbf{A}_{1}$ (step $\mathrm{T}_{3}$ ). The primitive $\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right.$ ] integrals are then contracted (step C), and horizontal RRs (HRRs) are used to shift angular momentum from the bra centers $\mathbf{A}_{3}, \mathbf{A}_{2}$, and $\mathbf{A}_{1}$ onto the ket centers $\mathbf{B}_{3}, \mathbf{B}_{2}$, and $\mathbf{B}_{1}$ (steps $\mathrm{T}_{4}, \mathrm{~T}_{5}$, and $\mathrm{T}_{6}$ ). The number of terms in each of these RRs is summarized in Table 2 for cyclic and chain operators. We now describe each step in detail.
3.1. Construct Shell-Pairs, -Quartets, and -Sextets. Beginning with a list of shells, a list of significant shell-pairs ${ }^{32}$ is constructed. By pairing these shell-pairs, a list of significant shell-quartets is created, and then by pairing the significant pairs and quartets, a list of significant shell-sextets is created. This process is critical for the efficiency of the overall algorithm and depends on the use of tight upper bounds for the target

Table 2. Number of RR Terms for Cyclic and Chain Operators

|  |  | operator |  |  |
| :---: | :---: | :---: | :---: | :---: |
| step | RR type | expression | $f_{12} g_{13} h_{23}$ | $f_{12} g_{13}$ |
| $\mathrm{~T}_{1}$ | VRR | eq 22 | 8 | 6 |
| $\mathrm{~T}_{2}$ | VRR | eq 24 | 10 | 7 |
| $\mathrm{~T}_{3}^{\prime}$ | VRR | eq 43 | 12 | 12 |
| $\mathrm{~T}_{3}$ | TRR | eq 27 | 6 | 6 |
| $\mathrm{~T}_{4}$ | HRR | eq 28 | 2 | 2 |
| $\mathrm{~T}_{5}$ | HRR | eq 29 | 2 | 2 |
| $\mathrm{~T}_{6}$ | HRR | eq 30 | 2 | 2 |

integrals. Such bounds are straightforward for two-electron integrals ${ }^{42-46}$ but are much more complicated for threeelectron integrals and, for example, the popular CauchySchwartz bound does not generalize easily. However, it is possible to construct a bound for each type of three-electron operator depending on the short- or long-range character of $f_{12}$, $g_{13}$ and (if present) $h_{23}$. We will discuss these in detail in part II of this series. ${ }^{47}$
3.2. Step O: Form Fundamental Integrals. Having chosen a significant shell-sextet, we replace the three twoelectron operators in its fundamental integral (eq 9) by their Laplace representations

$$
\begin{align*}
& f\left(r_{12}\right)=\int_{0}^{\infty} F\left(s_{1}\right) \exp \left(-s_{1} r_{12}^{2}\right) \mathrm{d} s_{1}  \tag{13a}\\
& g\left(r_{13}\right)=\int_{0}^{\infty} G\left(s_{2}\right) \exp \left(-s_{2} r_{13}^{2}\right) \mathrm{d} s_{2}  \tag{13b}\\
& h\left(r_{23}\right)=\int_{0}^{\infty} H\left(s_{3}\right) \exp \left(-s_{3} r_{23}^{2}\right) \mathrm{d} s_{3} \tag{13c}
\end{align*}
$$

Table 3 contains kernels $F(s)$ for a variety of important twoelectron operators $f\left(r_{12}\right)$. From the formulas in Table 3, one can also easily deduce the Laplace kernels for related functions, such as $f\left(r_{12}\right)^{2}, f\left(r_{12}\right) / r_{12}$, and $\nabla^{2} f\left(r_{12}\right)$. Integrating over $\mathbf{r}_{1}, \mathbf{r}_{2}$, and $\mathbf{r}_{3}$ then yields

$$
\begin{equation*}
[\mathbf{0}]=S_{1} S_{2} S_{3} \int_{0}^{\infty} \int_{0}^{\infty} \int_{0}^{\infty} F\left(s_{1}\right) G\left(s_{2}\right) H\left(s_{3}\right) w_{\mathbf{0}}(\mathbf{s}) \mathrm{d} \mathbf{s} \tag{14}
\end{equation*}
$$

where

$$
\begin{equation*}
w_{\mathbf{0}}(\mathbf{s})=\left[\frac{\pi^{3}}{\zeta_{1} \zeta_{2} \zeta_{3} D(\mathbf{s})}\right]^{3 / 2} \exp \left[-\frac{N(\mathbf{s})}{D(\mathbf{s})}\right] \tag{15}
\end{equation*}
$$

and $\boldsymbol{s}=\left(s_{1}, s_{2}, s_{3}\right)$. The numerator and denominator are

$$
\begin{align*}
N(\mathbf{s})= & \kappa_{12} s_{1}+\kappa_{13} s_{2}+\kappa_{23} s_{3}+ \\
& \left(\frac{\kappa_{12}}{\zeta_{3}}+\frac{\kappa_{13}}{\zeta_{2}}+\frac{\kappa_{23}}{\zeta_{1}}\right)\left(s_{1} s_{2}+s_{1} s_{3}+s_{2} s_{3}\right)  \tag{16a}\\
D(\mathbf{s})= & 1+\left[\frac{1}{\zeta_{1}}+\frac{1}{\zeta_{2}}\right] s_{1}+\left[\frac{1}{\zeta_{1}}+\frac{1}{\zeta_{3}}\right] s_{2}+\left[\frac{1}{\zeta_{2}}+\frac{1}{\zeta_{3}}\right] s_{3} \\
& +\frac{\zeta_{1}+\zeta_{2}+\zeta_{3}}{\zeta_{1} \zeta_{2} \zeta_{3}}\left(s_{1} s_{2}+s_{1} s_{3}+s_{2} s_{3}\right) \tag{16b}
\end{align*}
$$

where

$$
\begin{equation*}
\kappa_{i j}=\mathbf{Y}_{i j} \cdot \mathbf{Y}_{i j} \tag{17}
\end{equation*}
$$

Table 3. Laplace Kernels $F(s)$ for Various Two-Electron Operators $f\left(r_{12}\right)^{a}$

$$
\begin{array}{cc}
f\left(r_{12}\right) & F(s) \\
r_{12}^{n} \exp \left(-\lambda r_{12}\right) & \frac{2 \pi^{-1 / 2}}{(4 s)^{n / 2+1}} H_{n+1}\left(\frac{\lambda}{2 s^{1 / 2}}\right) \exp \left(-\frac{\lambda^{2}}{4 s}\right) \\
\left(r_{12}^{2}-R^{2}\right)^{n} \exp \left(-\lambda^{2} r_{12}^{2}\right) & \exp \left[-R^{2}\left(s-\lambda^{2}\right)\right] \delta^{(n)}\left(s-\lambda^{2}\right) \\
\left(r_{12}^{2}-R^{2}\right)^{n-1 / 2} \exp \left(-\lambda^{2} r_{12}^{2}\right) & \frac{\exp \left[-R^{2}\left(s-\lambda^{2}\right)\right] \theta\left(s-\lambda^{2}\right)}{\Gamma(-n+1 / 2)\left(s-\lambda^{2}\right)^{n+1 / 2}} \\
r_{12}^{2 n} \operatorname{erfc}\left(\lambda r_{12}\right) & \frac{-\pi^{-1 / 2}}{\Gamma(-n-1 / 2) s^{n+1}} \sum_{k=0}^{n}\binom{n}{k}\left(\frac{\lambda^{2}}{s-\lambda^{2}}\right)^{k+1 / 2} \frac{\theta\left(s-\lambda^{2}\right)}{k+1 / 2} \\
r_{12}^{2 n-1} \operatorname{erfc}\left(\lambda r_{12}\right) & \sum_{k=0}^{n}\binom{n}{k} \frac{s^{k-n-1 / 2}}{\Gamma(k-n+1 / 2)} \theta^{(k)}\left(s-\lambda^{2}\right) \\
r_{12}^{2 n} \operatorname{erfc}\left(\lambda r_{12}\right)^{2} & \frac{2 \lambda}{\pi s \sqrt{s-\lambda^{2}}} \sum_{k=0}^{n}\binom{n}{k}(3 / 2)_{k} \frac{\theta^{(n-k)\left(s-2 \lambda^{2}\right)}}{\left(\lambda^{2}-s\right)^{k}} \sum_{j=0}^{k} \frac{(-k)_{j}}{(3 / 2)_{j}}\left(\lambda^{2} / s\right)^{j}
\end{array}
$$

${ }^{a}$ The variable $n$ is an integer. $\Gamma$ is the gamma function. $H_{n}$ is a Hermite polynomial; erfc is the complementary error function, and $(a)_{j}$ is a Pochhammer symbol. $\delta^{(k)}$ and $\theta^{(k)}$ are the kth derivatives of the Dirac delta function and Heaviside step function, respectively. ${ }^{56}$
is the squared length of the vector

$$
\begin{equation*}
\mathbf{Y}_{i j}=\mathbf{Z}_{i}-\mathbf{Z}_{j} \tag{18}
\end{equation*}
$$

between the $i$ th and $j$ th Gaussian product centers.
For reasons that will become clear later, it is convenient to introduce the generalized fundamental integral

$$
\begin{equation*}
[\mathbf{0}]^{\mathbf{m}}=S_{1} S_{2} S_{3} \int_{0}^{\infty} \int_{0}^{\infty} \int_{0}^{\infty} F\left(s_{1}\right) G\left(s_{2}\right) H\left(s_{3}\right) w_{\mathbf{m}}(\mathbf{s}) \mathrm{d} \mathbf{s} \tag{19}
\end{equation*}
$$

where

$$
\begin{equation*}
w_{\mathbf{m}}(\mathbf{s})=\frac{s_{1}^{m_{1}} s_{2}^{m_{2}} s_{3}^{m_{3}}}{D(\mathbf{s})^{m_{1}+m_{2}+m_{3}}}\left[\frac{s_{1} s_{2}+s_{1} s_{3}+s_{2} s_{3}}{D(\mathbf{s})}\right]^{m_{4}} w_{\mathbf{0}}(\mathbf{s}) \tag{20}
\end{equation*}
$$

and the auxiliary index vector $\mathbf{m}=\left(m_{1}, m_{2}, m_{3}, m_{4}\right)$.
To form an $\left[a_{1} a_{2} a_{3} \mid b_{1} b_{2} b_{3}\right]$ class with a cyclic operator, we require all $[0]^{\mathrm{m}}$ with

$$
\begin{align*}
& 0 \leq m_{1} \leq a_{1}+a_{2}+b_{1}+b_{2}  \tag{21a}\\
& 0 \leq m_{2} \leq a_{1}+a_{3}+b_{1}+b_{3}  \tag{21b}\\
& 0 \leq m_{3} \leq a_{2}+a_{3}+b_{2}+b_{3}  \tag{21c}\\
& 0 \leq m_{4} \leq a_{1}+a_{2}+a_{3}+b_{1}+b_{2}+b_{3} \tag{21d}
\end{align*}
$$

To form an $\left[a_{1} a_{2} a_{3} \mid b_{1} b_{2} b_{3}\right]$ class with a chain operator, the ranges of $m_{1}, m_{2}$, and $m_{4}$ are as in (eq 21) but $m_{3}=0$.

To construct an $\langle a a l a a\rangle$ class of two-electron integrals, one needs only $O(a)[0]^{(m)}$ integrals. ${ }^{32}$ However, it follows from eq 21 that, to construct an 〈aaalaaa〉 class of three-electron integrals, we need $O\left(a^{3}\right)$ (for a chain operator) or $O\left(a^{4}\right)$ (for a cyclic operator) $[0]^{\mathrm{m}}$ integrals. This highlights the importance of computing these $[0]^{\mathrm{m}}$ efficiently. If at least one of the twoelectron operators is a GTG, the [0] ${ }^{\mathrm{m}}$ can be found in closed form. ${ }^{57,58}$ Otherwise, they can be reduced to one- or twodimensional integrals, which can then be evaluated by various numerical techniques. This step can consume a significant fraction of the total computation time, ${ }^{30}$ and a comprehensive treatment of suitable numerical methods merits a detailed discussion, which we will present in part III of this series. ${ }^{48}$
3.3. Step $\mathrm{T}_{1}$ : Build Momentum on Center $\mathrm{A}_{3}$. Given a set of $[\mathbf{0}]^{\mathrm{m}}$, integrals of higher angular momentum can be
obtained recursively following Obara and Saika. ${ }^{26,27}$ Whereas VRRs for two-electron integrals have been widely studied, VRRs for three-electron integrals have not, except for GTGs. ${ }^{10,49-54}$

The $\mathrm{T}_{1}$ step generates $\left[\mathbf{a}_{3}\right]^{\mathrm{m}}$ from $[\mathbf{0}]^{\mathrm{m}}$ via the 8 -term VRR (see the Appendix for a detailed derivation)

$$
\begin{align*}
{\left[\mathbf{a}_{3}^{+}\right]^{\mathbf{m}}=} & \left(\mathbf{Z}_{3}-\mathbf{A}_{3}\right)\left[\mathbf{a}_{3}\right]^{\{0\}}+\zeta_{1} \zeta_{2} \mathbf{Y}_{13}\left[\mathbf{a}_{3}\right]^{\{2\}}+\zeta_{1} \zeta_{2} \mathbf{Y}_{23}\left[\mathbf{a}_{3}\right]^{\{3\}} \\
& +\left(\zeta_{1} \mathbf{Y}_{13}+\zeta_{2} \mathbf{Y}_{23}\right)\left[\mathbf{a}_{3}\right]^{\{4\}}+\frac{\mathbf{a}_{3}}{2 \zeta_{3}}\left\{\left[\mathbf{a}_{3}^{-}\right]^{\{0\}}-\zeta_{1} \zeta_{2}\left[\mathbf{a}_{3}^{-}\right]^{\{2\}}\right. \\
& -\zeta_{1} \zeta_{2}\left[\mathbf{a}_{3}^{-}\{[3\}\right.  \tag{22}\\
]^{23\}} & \left.\left(\zeta_{1}+\zeta_{2}\right)\left[\mathbf{a}_{3}^{-}\right]^{\{4\}}\right\}
\end{align*}
$$

where the superscript + or - denotes an increment or decrement of one unit of Cartesian angular momentum. (Thus, $\mathbf{a}^{ \pm}$is analogous to $\mathbf{a} \mathbf{1}_{i}$ in the notation of Obara and Saika.) The value in the curly superscript indicates which component of the auxiliary index vector $\mathbf{m}$ is incremented.

For a chain operator, the $\{3\}$ terms disappear, yielding the 6term RR

$$
\begin{align*}
{\left[\mathbf{a}_{3}^{+}\right]^{\mathbf{m}}=} & \left(\mathbf{Z}_{3}-\mathbf{A}_{3}\right)\left[\mathbf{a}_{\mathbf{3}}\right]^{\{0\}}+\zeta_{1} \zeta_{2} \mathbf{Y}_{13}\left[\mathbf{a}_{3}\right]^{\{2\}}+\left(\zeta_{1} \mathbf{Y}_{13}+\zeta_{2} \mathbf{Y}_{23}\right)\left[\mathbf{a}_{3}\right]^{\{4\}} \\
& +\frac{\mathbf{a}_{3}}{2 \zeta_{3}}\left\{\left[\mathbf{a}_{3}^{-}\right]^{\{0\}}-\zeta_{1} \zeta_{2}\left[\mathbf{a}_{3}^{-}\right]^{22\}}-\left(\zeta_{1}+\zeta_{2}\right)\left[\mathbf{a}_{3}^{-}\right]^{[4\}}\right\} \tag{23}
\end{align*}
$$

It is satisfying to note that, by setting $\zeta_{2}=0$ in (eq 23), we recover the Obara-Saika two-electron RR.
3.4. Step $T_{2}$ : Build Momentum on Center $A_{2}$. The $T_{2}$ step forms $\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]$ from $\left[\mathbf{a}_{3}\right]^{\mathrm{m}}$ via the 10 -term RR

$$
\begin{align*}
{\left[\mathbf{a}_{2}^{+} \mathbf{a}_{3}\right]^{\mathbf{m}}=} & \left(\mathbf{Z}_{2}-\mathbf{A}_{2}\right)\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{0\}}+\zeta_{1} \zeta_{3} \mathbf{Y}_{12}\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{1\}} \\
& -\zeta_{1} \zeta_{3} \mathbf{Y}_{23}\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{3\}}+\left(\zeta_{1} \mathbf{Y}_{12}-\zeta_{3} \mathbf{Y}_{23}\right)\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{4\}} \\
& +\frac{\mathbf{a}_{2}}{2 \zeta_{2}}\left\{\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{0\}}-\zeta_{1} \zeta_{3}\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{1\}}-\zeta_{1} \zeta_{3}\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{3\}}\right. \\
& \left.-\left(\zeta_{1}+\zeta_{3}\right)\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{4\}}\right\}+\frac{\mathbf{a}_{3}}{2}\left\{\zeta_{1}\left[\mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]^{\{3\}}\right. \\
& \left.+\left[\mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]^{\{4\}}\right\} \tag{24}
\end{align*}
$$

For a chain operator, the $\{3\}$ terms disappear, yielding the 7 term VRR

$$
\begin{align*}
{\left[\mathbf{a}_{2}^{+} \mathbf{a}_{3}\right]^{\mathbf{m}}=} & \left(\mathbf{Z}_{2}-\mathbf{A}_{2}\right)\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{0\}}+\zeta_{1} \zeta_{3} \mathbf{Y}_{12}\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{1\}} \\
& +\left(\zeta_{1} \mathbf{Y}_{12}-\zeta_{3} \mathbf{Y}_{23}\right)\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{4\}} \\
& +\frac{\mathbf{a}_{2}}{2 \zeta_{2}}\left\{\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{0\}}-\zeta_{1} \zeta_{3}\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{1\}}\right. \\
& \left.-\left(\zeta_{1}+\zeta_{3}\right)\left[\mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{4\}}\right\}+\frac{\mathbf{a}_{3}}{2}\left[\mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]^{\{4\}} \tag{25}
\end{align*}
$$

3.5. Step $T_{3}$ : Transfer Momentum to Center $A_{1}$. The $T_{3}$ step generates $\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right]$ from $\left[\mathbf{a}_{2} \mathbf{a}_{3}\right]$. There are two possible ways to do this. The first, which we call step $\mathrm{T}_{3}^{\prime}$, is to build angular momentum directly on $\mathbf{A}_{1}$ using the 12-term VRR (eq 43). However, this is computationally expensive and we choose to avoid it. A second option exploits the translational invariance

$$
\begin{equation*}
\sum_{j=1}^{3}\left(\nabla_{\mathbf{A}_{j}}+\nabla_{\mathbf{B}_{j}}\right)\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right]=\mathbf{0} \tag{26}
\end{equation*}
$$

to derive the 6-term TRR

$$
\begin{align*}
{\left[\mathbf{a}_{1}^{+} \mathbf{a}_{2} \mathbf{a}_{3}\right]=} & \frac{\mathbf{a}_{1}}{2 \zeta_{1}}\left[\mathbf{a}_{1}^{-} \mathbf{a}_{2} \mathbf{a}_{3}\right]+\frac{\mathbf{a}_{2}}{2 \zeta_{1}}\left[\mathbf{a}_{1} \mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]+\frac{\mathbf{a}_{3}}{2 \zeta_{1}}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]-\frac{\zeta_{2}}{\zeta_{1}}\left[\mathbf{a}_{1} \mathbf{a}_{2}^{+} \mathbf{a}_{3}\right] \\
& -\frac{\zeta_{3}}{\zeta}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}^{+}\right] \\
& -\frac{\beta_{1}\left(\mathbf{A}_{1}-\mathbf{B}_{1}\right)+\beta_{2}\left(\mathbf{A}_{2}-\mathbf{B}_{2}\right)+\beta_{3}\left(\mathbf{A}_{3}-\mathbf{B}_{3}\right)}{\zeta_{1}}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right] \tag{27}
\end{align*}
$$

which transfers momentum between centers that host different electrons.
3.6. Step C: Contraction. At this stage, following the HGP algorithm, ${ }^{28}$ we contract $\left[\mathbf{a}_{1} \mathbf{a}_{2} a_{3} \mid 000\right]$ to form $\left\langle\mathbf{a}_{1} \mathbf{a}_{2} a_{3} \mid 000\right\rangle$. We can perform the contraction at this point because all of the subsequent RRs are independent of the contraction coefficients and exponents. More details about this contraction step can be found in ref 32 .
3.7. Steps $T_{4}$ to $T_{6}$ : Shift Momentum to Ket Centers. We shift momentum to $\mathbf{B}_{3}, \mathbf{B}_{2}$, and $\mathbf{B}_{1}$ from $\mathbf{A}_{3}, \mathbf{A}_{2}$, and $\mathbf{A}_{1}$, respectively, using the 2-term HRRs

$$
\begin{align*}
& \left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{3}^{+}\right\rangle=\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}^{+} \mid \mathbf{b}_{3}\right\rangle+\left(\mathbf{A}_{3}-\mathbf{B}_{3}\right)\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{3}\right\rangle  \tag{28}\\
& \left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{2}^{+} \mathbf{b}_{3}\right\rangle=\left\langle\mathbf{a}_{1} \mathbf{a}_{2}^{+} \mathbf{a}_{3} \mid \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle+\left(\mathbf{A}_{2}-\mathbf{B}_{2}\right)\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle  \tag{29}\\
& \left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{1}^{+} \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle=\left\langle\mathbf{a}_{1}^{+} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle+\left(\mathbf{A}_{1}-\mathbf{B}_{1}\right)\left\langle\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} \mid \mathbf{b}_{1} \mathbf{b}_{2} \mathbf{b}_{3}\right\rangle \tag{30}
\end{align*}
$$

## 4. CONCLUDING REMARKS

In this article, we have presented a general algorithm to construct three-electron integrals over Gaussian basis functions of arbitrary angular momentum from fundamental (momentumless) integrals. The algorithm is based on vertical, transfer, and horizontal RRs in the spirit of the Head-Gordon-Pople algorithm. In part II of this series, we will report detailed investigations of upper bounds on these integrals. In part III, we will discuss efficient methods for computing the fundamental integrals. Our approach can be extended to four-electron integrals, and we will also report results on this soon.

## APPENDIX. DERIVATION OF VRRS

In this appendix, we follow the Ahlrichs approach ${ }^{59}$ to derive a VRR for the construction of $\left[\mathbf{a}_{1}\right]^{\mathrm{m}}$ integrals.

Defining the scaled gradient operator

$$
\begin{equation*}
\hat{D}_{\mathbf{A}_{1}}=\frac{\nabla_{\mathbf{A}_{1}}}{2 \alpha_{1}} \tag{31}
\end{equation*}
$$

we can write the Boys relation ${ }^{22}$

$$
\begin{equation*}
\left[\mathbf{a}_{1}^{+}\right]=\hat{D}_{\mathbf{A}_{1}}\left[\mathbf{a}_{1}\right]+\frac{\mathbf{a}_{1}}{2 \alpha_{1}}\left[\mathbf{a}_{1}^{-}\right] \tag{32}
\end{equation*}
$$

which connects an integral of higher momentum to an integral derivative with respect to a coordinate of $\mathbf{A}_{1}$.

In operator form, this can be written as

$$
\begin{equation*}
\left[\mathbf{a}_{1}^{+}\right]=\hat{M}_{\mathbf{a}_{1}} \hat{D}_{\mathbf{A}_{1}}[\mathbf{0}]+\frac{\mathbf{a}_{1}}{2 \alpha_{1}}\left[\mathbf{a}_{1}^{-}\right] \tag{33}
\end{equation*}
$$

Substituting the chain rule expression

$$
\begin{equation*}
\hat{D}_{\mathbf{A}_{1}}=\frac{\nabla_{\mathbf{A}_{1}} S_{1}}{2 \alpha_{1}} \frac{\partial}{\partial S_{1}}+\frac{\nabla_{\mathbf{A}_{1}} \kappa_{12}}{2 \alpha_{1}} \frac{\partial}{\partial \kappa_{12}}+\frac{\nabla_{\mathbf{A}_{1}} \kappa_{13}}{2 \alpha_{1}} \frac{\partial}{\partial \kappa_{13}} \tag{34}
\end{equation*}
$$

into eq 33 using the identities

$$
\begin{align*}
& \frac{\partial[\mathbf{0}]^{\mathbf{m}}}{\partial S_{1}}=S_{1}^{-1}[\mathbf{0}]^{\{0\}}  \tag{35}\\
& \frac{\partial[\mathbf{0}]^{\mathbf{m}}}{\partial \kappa_{12}}=-\zeta_{1} \zeta_{2} \zeta_{3}[\mathbf{0}]^{\{1\}}-\zeta_{1} \zeta_{2}[\mathbf{0}]^{\{4\}}  \tag{36}\\
& \frac{\partial[\mathbf{0}]^{\mathbf{m}}}{\partial \kappa_{13}}=-\zeta_{1} \zeta_{2} \zeta_{3}[\mathbf{0}]^{\{2\}}-\zeta_{1} \zeta_{3}[\mathbf{0}]^{\{4\}} \tag{37}
\end{align*}
$$

the commutator property

$$
\begin{equation*}
\hat{M}_{\mathbf{a}_{1}} p=p \hat{M}_{\mathbf{a}_{1}}+\mathbf{a}_{1} \rho \hat{M}_{\mathbf{a}_{1}^{-}} \tag{38}
\end{equation*}
$$

where $p$ is linear in $\mathbf{A}_{1}$ and $\rho$ is its derivative, and the identities

$$
\begin{align*}
& \hat{D}_{\mathbf{A}_{1}}\left(\mathbf{Z}_{1}-\mathbf{A}_{1}\right)=-\frac{\beta_{1}}{2 \alpha_{1} \zeta_{1}}  \tag{39}\\
& \hat{D}_{\mathbf{A}_{1}} \mathbf{Y}_{12}=\hat{D}_{\mathbf{A}_{1}} \mathbf{Y}_{13}=\frac{1}{2 \zeta_{1}} \tag{40}
\end{align*}
$$

one eventually obtains the 8-term RR for building on $\mathbf{A}_{1}$

$$
\begin{align*}
{\left[\mathbf{a}_{1}^{+}\right]^{\mathbf{m}}=} & \left(\mathbf{Z}_{1}-\mathbf{A}_{1}\right)\left[\mathbf{a}_{1}\right]^{\{0\}}-\zeta_{2} \zeta_{3} \mathbf{Y}_{12}\left[\mathbf{a}_{1}\right]^{\{1\}}-\zeta_{2} \zeta_{3} \mathbf{Y}_{13}\left[\mathbf{a}_{1}\right]^{\{2\}} \\
& -\left(\zeta_{2} \mathbf{Y}_{12}+\zeta_{3} \mathbf{Y}_{13}\right)\left[\mathbf{a}_{1}\right]^{4\}} \\
& +\frac{\mathbf{a}_{1}}{2 \zeta_{1}}\left\{\mathbf{a}_{1}^{-}\right]^{\{0\}}-\zeta_{2} \zeta_{3}\left[\mathbf{a}_{1}^{-}\right]^{\{1\}}-\zeta_{2} \zeta_{3}\left[\mathbf{a}_{1}^{-}\right]^{\{2\}} \\
& \left.-\left(\zeta_{2}+\zeta_{3}\right)\left[\mathbf{a}_{1}^{-}\right]^{\{4\}}\right\} \tag{41}
\end{align*}
$$

Eq 22, which builds on $\mathbf{A}_{3}$, can be derived similarly. However, for chain operators, the RR that builds on $\mathrm{A}_{1}$ does not shed terms, and it is therefore cheaper to build on $\mathbf{A}_{3}$ than on $\mathbf{A}_{1}$.

Eq 24 can be derived using the relation

$$
\begin{equation*}
\left[\mathbf{a}_{2}^{+} \mathbf{a}_{3}\right]^{\mathbf{m}}=\hat{M}_{\mathbf{a}_{3}}\left[\mathbf{a}_{2}^{+}\right]^{\mathbf{m}} \tag{42}
\end{equation*}
$$

and the 12-term VRR for building on $\mathrm{A}_{1}$ in step $\mathrm{T}_{3}^{\prime}$ is

$$
\begin{align*}
{\left[\mathbf{a}_{1}^{+} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\mathbf{m}}=} & \hat{M}_{\mathbf{a}_{3}} \hat{\mathbf{a}}_{\mathbf{a}_{2}}\left[\mathbf{a}_{1}^{+}\right]^{\mathbf{m}} \\
= & \left(\mathbf{Z}_{1}-\mathbf{A}_{1}\right)\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{0\}}-\zeta_{2} \zeta_{3} \mathbf{Y}_{12}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3} 1^{\{1\}}\right. \\
& -\zeta_{2} \zeta_{3} \mathbf{Y}_{13}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{2\}}-\left(\zeta_{2} \mathbf{Y}_{12}+\zeta_{3} \mathbf{Y}_{13}\right)\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{4\}} \\
& +\frac{\mathbf{a}_{1}}{2 \zeta_{1}}\left\{\mathbf{a}_{1}^{-} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{0\}}-\zeta_{2} \zeta_{3}\left[\mathbf { a } _ { 1 } ^ { - } \mathbf { a } _ { 2 } \mathbf { a } _ { 3 } \left\{11^{\{1\}}-\zeta_{2} \zeta_{3}\left[\mathbf{a}_{1}^{-} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{2\}}\right.\right. \\
& \left.-\left(\zeta_{2}+\zeta_{3}\right)\left[\mathbf{a}_{1}^{-} \mathbf{a}_{2} \mathbf{a}_{3}\right]^{\{4\}}\right\}+\frac{\mathbf{a}_{2}}{2}\left\{\zeta_{3}\left[\mathbf{a}_{1} \mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{1\}}\right. \\
& \left.+\left[\mathbf{a}_{\mathbf{1}} \mathbf{a}_{2}^{-} \mathbf{a}_{3}\right]^{\{4\}}\right\}+\frac{\mathbf{a}_{3}}{2}\left\{\zeta_{2}\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]^{\{2\}}+\left[\mathbf{a}_{1} \mathbf{a}_{2} \mathbf{a}_{3}^{-}\right]^{\{4\}}\right\} \tag{43}
\end{align*}
$$
